

Architecture Development Part 5: Interoperability- FHIR Data Exchange with HAPI-FHIR

response.code.png

Questions:

1. What is the process to create a new FHIR resource using Postman and HAPI FHIR server?

To create a new FHIR resource, first open Postman and create a new request. Then change the HTTP method to POST and enter the resource endpoint, for example `http://localhost:8090/fhir/Practitioner`. Next, copy or write the JSON body for the resource, paste it into the Body tab and set the body type to raw JSON. After that, send the request to the HAPI FHIR server. If the request is valid and the resource is created successfully, the server returns 201 Created and includes the new resource with an assigned ID in the response.

2. What is the process to manage authentication when using Postman with a HAPI FHIR server?

Authentication is managed in Postman by checking what security method the HAPI FHIR server requires and then adding the proper credentials to the request. In general, this is done in the Authorization tab or by adding the required headers manually. For example, if the server requires a token, you place that token in the authorization settings or request headers before sending the request. The guide also notes that you may log in to Postman if required, while the REST API documentation helps identify the request format, authentication strategy and response structure needed to interact correctly with the server.

3. How can you handle error responses from the HAPI FHIR server when using Postman?

Error responses are handled by checking the HTTP status code and the response body returned in Postman. For example, if the request is not formatted correctly, the server may return 400 Bad Request. You should then review the request URL, method, JSON structure and headers, correct the mistake and resend the request. In this activity, a successful request is confirmed by 201 Created, so any other code shows that something needs to be fixed before the resource can be created. Postman makes this easier because it shows the full status code, headers and response body for troubleshooting.
